National Center for Computational Toxicology

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

Disclaimer: views are those of the presenter and do not necessarily reflect Agency policy nor imply endorsement of software used here

Overview

- ❖ scope of the problem
 - *assessing the toxicity of environmental chemicals*

- ❖ high-throughput screening (HTS)
 - *launching from the drug-discovery paradigm*

- ❖ computational (*in silico*) models
 - *molecular pathways and complex systems*

- ❖ virtual tissues
 - *building blocks for a virtual embryo*

Environmental chemicals

- ❖ need to understand health risks associated with 10K-30K chemicals in commerce and the environment
- ❖ current testing strategy is low throughput, costly, and relies on high-dose effects in animal studies
- ❖ only a minor fraction of chemicals of concern have data in sufficient depth or detail for risk assessment (IRIS <1K)
- ❖ scientific and practical needs for a different way to test chemicals and predict toxicities more efficiently

July 2007

THE NATIONAL ACADEMIES REPORT IN BRIEF

Toxicity Testing in the 21st Century: A Vision and a Strategy

Advances in molecular biology, biotechnology, and other fields are paving the way for major improvements in how scientists evaluate the health risks posed by potentially toxic chemicals found at low levels in the environment. These advances would make toxicity testing quicker, less expensive, and more directly relevant to human exposures. They could also reduce the need for animal testing by substituting more laboratory tests based on human cells. This National Research Council report creates a far-reaching vision for the future of toxicity testing.

Toxicity tests on laboratory animals are conducted to evaluate chemicals—including medicines, food additives, and industrial, consumer, and agricultural chemicals—for their potential to cause cancer, birth defects, and other adverse health effects. Information from toxicity testing serves as an important part of the basis for public health and regulatory decisions concerning toxic chemicals. Current test methods were developed incrementally over the past 50 to 60 years and are conducted using laboratory animals, such as rats and mice. Using the results of animal tests to predict human health effects involves a number of assumptions and extrapolations that remain controversial. Test animals are often exposed to higher doses than would be expected for typical human exposures, requiring assumptions about effects at lower doses or exposures. Test animals are typically observed for overt signs of adverse health effects, which provide little information about biological changes leading to such health effects. Often controversial uncertainty factors must be applied to account for differences between test animals and humans. Finally, use of animals in testing is expensive and time consuming, and it sometimes raises ethical issues.

Today, toxicological evaluation of chemicals is poised to take advantage of the on-going revolution in biology and biotechnology. This revolution is making it increasingly possible to study the effects of chemicals using cells, cellular components, and tissues—preferably of human origin—rather than whole animals. These powerful new approaches should help to address a number of challenges facing the

POLICYFORUM

TOXICOLOGY

Transforming Environmental Health Protection

Francis S. Collins,^{1*} George M. Gray,^{2*} John R. Bucher^{3*}

We propose a shift from primarily in vivo animal studies to in vitro assays, in vivo assays with lower organisms, and computational modeling for toxicity assessments.

In 2005, the U.S. Environmental Protection Agency (EPA), with support from the U.S. National Toxicology Program (NTP), funded a project at the National Research Council (NRC) to develop a long-range vision for toxicity testing and a strategic plan for implementing that vision. Both agencies wanted future toxicity testing and assessment paradigms to meet evolving regulatory needs. Challenges include the large numbers of substances that need to be tested and how to incorporate recent advances in molecular toxicology, computational sciences, and information technology, to rely increasingly on human as opposed to animal data; and to offer increased efficiency in design and costs (1–5). In response, the NRC Committee on Toxicity Testing and Assessment of Environmental Agents produced two reports that reviewed current toxicity testing, identified key issues, and developed a vision and implementation strategy to create a major shift in the assessment of chemical hazard and risk (6, 7). Although the NRC reports have laid out a solid theoretical rationale, comprehensive and rigorously gathered data (and comparisons with historical animal data) will determine whether the hypothesized improvements will be realized in practice. For this purpose, NTP, EPA, and the National Institutes of Health Chemical Genomics Center (NCGC) (organizations with expertise in experimental toxicology, computational toxicology, and high-throughput technologies, respectively) have established a collaborative research program.

EPA, NCGC, and NTP Joint Activities
In 2004, the NTP released its vision and roadmap for the 21st century (1), which established initiatives to integrate high-throughput screening (HTS) and other automated screening assays into its testing program. In 2005, the EPA established the National Center for Computational Toxicology (NCCT). Through these initiatives, NTP and EPA, with the NCGC, are promoting the evolution of toxicology from a predominantly observational science at the level of disease-specific models in vivo to a predominantly predictive science focused on broad inclusion of target-specific, mechanism-based, biological observations in vitro (1, 4) (see figure, below).

Toxicity pathways. In vitro and in vivo tools are being used to identify cellular responses after chemical exposure expected to result in adverse health effects (7). HTS methods are a primary means of discovery for drug development, and screening of >100,000 compounds per day is routine (8). However, drug-discovery HTS methods traditionally test compounds at one concentration, usually between 2 and 10 μM, and tolerate high false-negative rates. In contrast, in the EPA, NCGC, and NTP combined effort, all compounds are tested at as many as 15 concentrations, generally ranging from ~5 nM to ~100 μM, to generate a concentration-response curve (9). This approach is highly reproducible, produces significantly lower false-positive and false-negative rates than the traditional HTS methods (9), and facilitates multiassay comparisons. Finally, an informatics platform has been built to compare results among HTS screens; this is being expanded to allow comparisons with historical toxicologic NTP and EPA data (<http://ncgc.nih.gov/pub/openshs>). HTS data collected by EPA and NTP, as well as by the NCGC and Other Molecular Libraries Initiative centers (<http://mli.nih.gov/>), are being made publicly available through Web-based databases [e.g., PubChem (<http://pubchem.ncbi.nlm.nih.gov/>)]. In addition,

Human experience	Standard rodent toxicological tests	Alternative animal models	Biochemical- and cell-based in vitro assays
1–3 studies/year	10–100/year	100–10,000/year	>10,000/day

High Throughput Screening (HTS)

- ❖ uses automation to rapidly identify active compounds that modulate a particular biomolecular target or pathway
- ❖ activities are tested in an ‘assay’ using microtiter plates and a vehicle of DMSO
- ❖ assays are cell-based or cell-free (biochemical) systems and utilize recombinant technologies and human cells
- ❖ provides starting point for functional understanding of the particular biochemical process in drug development

HTS predictive modeling

Challenges and Opportunities

1. What fundamental targets emerge as we catalogue over a billion instances of *in vitro* perturbation?
2. What predictive signatures and pathways of toxicity will be unlocked from these HTS data?
3. How can we apply these data to different domains (e.g., predicting liver disease or developmental toxicity)?
4. Holy Grail: conquer the *in silico* reconstruction of tissues to evaluate biological plausibility of predictive signatures.

Developmental Toxicity

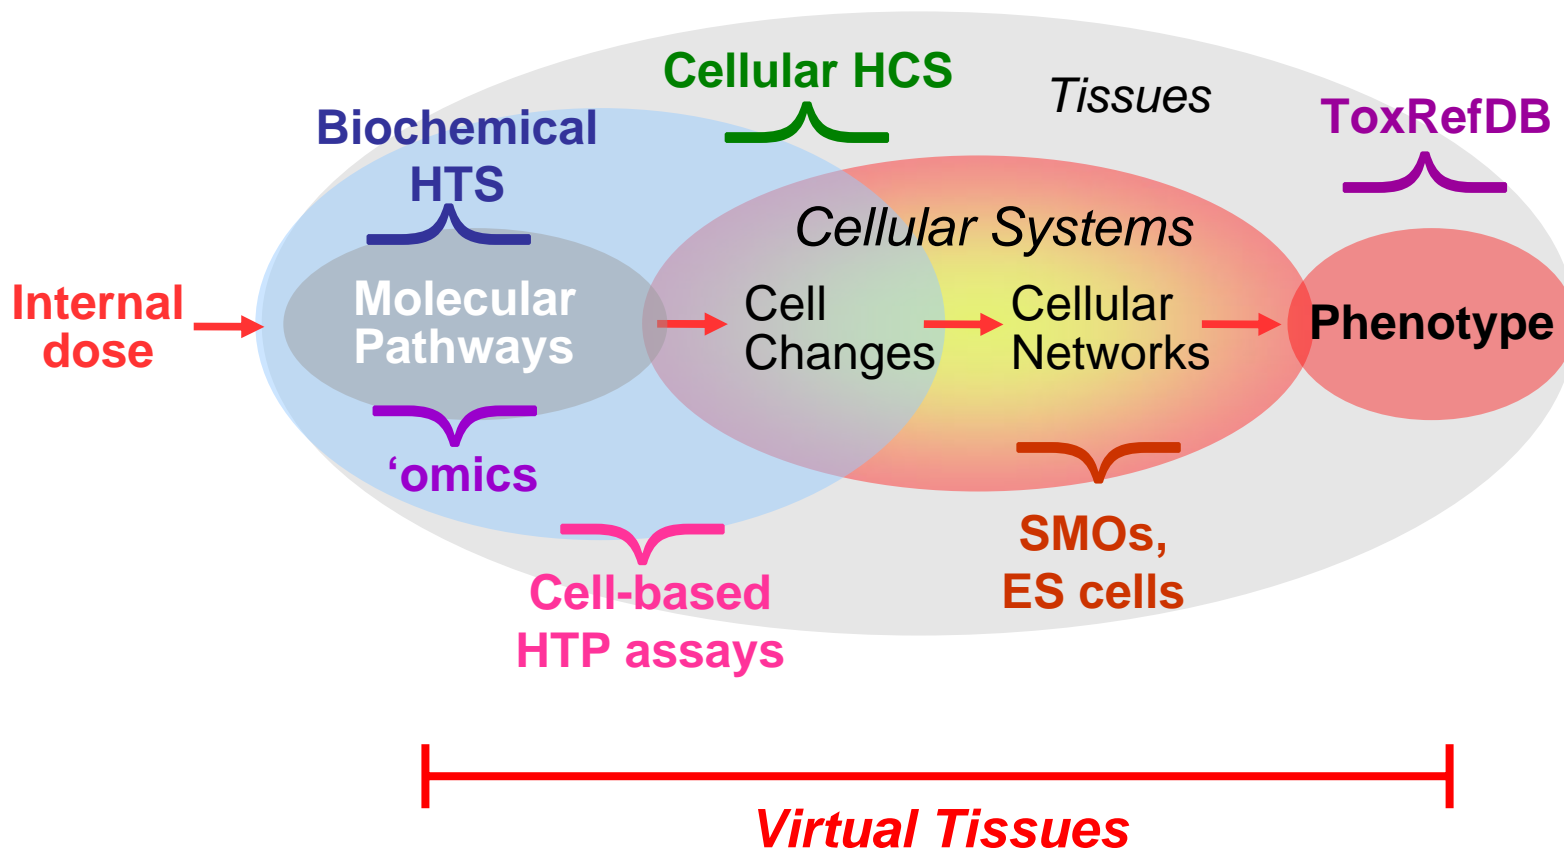

- 
- ❖ chemical perturbation during formative stages of the reproductive cycle affecting:
 - embryo and fetal development (birth defects)
 - postnatal development (disabilities)
 - fertility and reproduction
 - general children's health

Prenatal development is a system within a system

Factors underlying this complexity

1. **TIMING:** morphogenesis and differentiation require precisely timed genetic signals and responses
2. **SENSITIVITY:** metabolic and regulatory pathways are prone to genetic errors and environmental disruptions
3. **MULTIPLICITY:** simple lesions propagated to complex phenotypes & complex lesions → simple phenotypes
4. **MATERNAL:** impact of maternal exposure biology and physiology during prenatal and lactational stages

ToxCast™ Bioactivity Profiling

ToxRefDB

Toxicity Reference Database

- ❖ **source data:** 2073 guideline studies for 480 chemicals, mostly pesticides (>\$2B worth)
- ❖ **prenatal studies:** 751, mostly rat and rabbit, testing 387 chemicals (283 chemicals tested in both species)
- ❖ **annotation:** 988 terms for maternal and fetal effects based on enhanced *DevTox.org* lexicon
- ❖ **endpoints:** lowest effect levels for maternal (mLEL) and developmental (dLEL) parameters and cLELs

Morphogenetic processes

Core developmental processes

- patterning (sets up future events)
- timing (clocks and oscillators)
- differentiation (cell diversification)
- morphogenesis (tissue organization)

Cellular primitives

- growth (proliferation)
- death (apoptosis)
- differentiation (function)
- adhesion (DAH)
- shape (geometry)
- motility (cell migration)
- ECM (remodeling)

Morphogenetic movements

- folding
- epiboly
- convergent extension
- branching morphogenesis
- cell condensation
- cell sorting
- trans-differentiation
- cavitation
- involution
- tractional forces

VT: Virtues for Systems Modeling

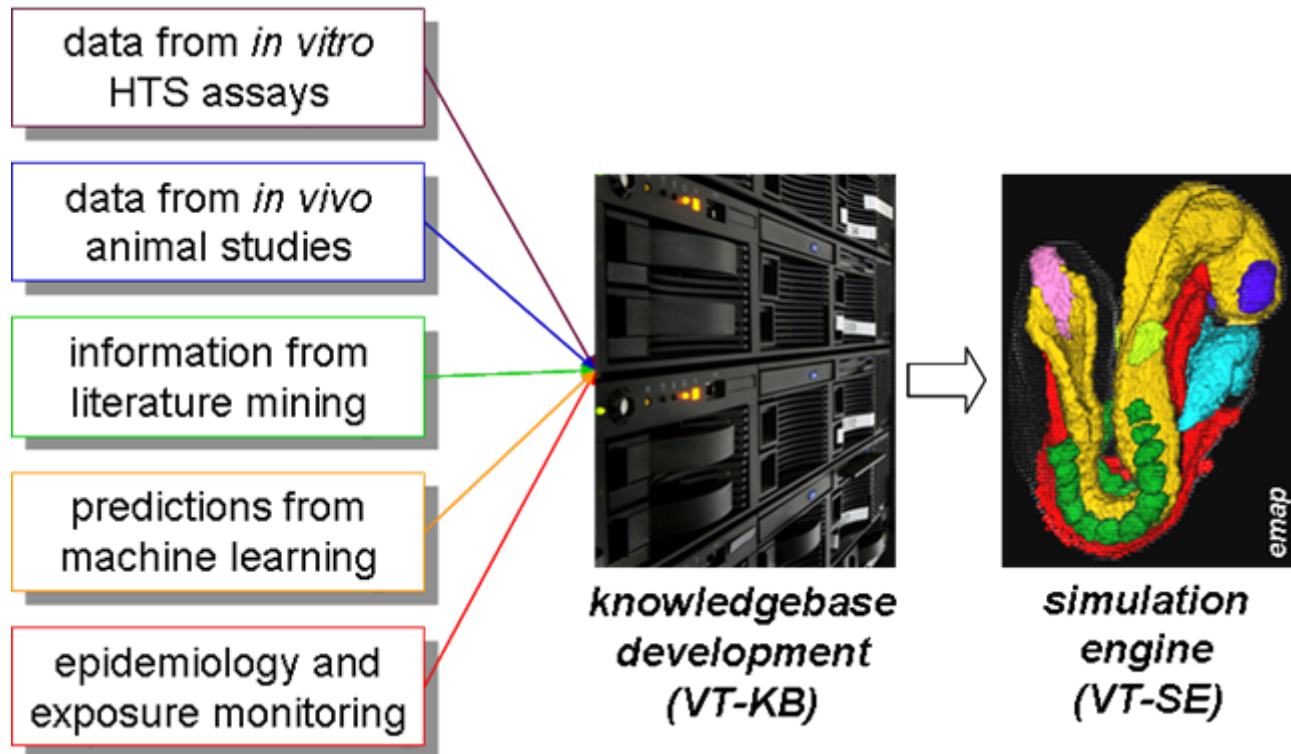

- ❖ incorporate knowledge of embryology and cell signaling pathways relevant to developmental processes
- ❖ enable the emergence of higher-order of organization using cells as autonomous agents
- ❖ implement predictive signatures from *in vitro* profiles (ToxCast) and analyze developmental trajectories
- ❖ determine biological plausibility of the predictors based on *in vivo* profiles (ToxRefDB)
