

IMS Question & Test Interoperability XML Binding Specification

**Final Specification
Version 1.0**

About This Document

Title	IMS Question & Test Interoperability XML Binding Specification
Authors	Colin Smythe and Eric Shepherd
Version	Version 1.0
Version Date	5 th June, 2000
Status	Final Specification.
Summary	This document describes the Question & Test Interoperability XML binding for the corresponding information model. The XML encoding is based on the W3C XML specification version 1.0. A mixture of attribute and tagged forms is used.
Revision Information	Last revised 5 th June, 2000
Purpose	Defines how the Question & Test Interoperability Information Model is encoded in XML by IMS.
Document Location	http://www.imsproject.org/question/qtbinding01.html

1. Introduction

1.1 Overview

The IMS Question & Test Interoperability XML Binding describes the Document Type Definition (DTD) and XML Data Representation (XDR) that are used to provide interoperability between question and test systems, particularly those for distributed learning. The key interoperable data structures are those of:

- Assessment – the basic test unit;
- Section – a container for groups of sections and items which support a common objective;
- Item – the fundamental self-contained question/response block within which the individual questions are contained.

Version 1.0 of the eXtensible Markup Language (XML) specification of the World Wide Web Consortium (W3C) is used. A DTD and XDR have been defined that are capable of representing the Assessment, Section and Item objects in any appropriate combination.

1.2 Scope & Context

This document is the IMS Question & Test Interoperability (Q&TI) XML Binding Specification. As such it will be used as the basis for the production of the following documents:

- IMS Question & Test Interoperability XML DTD;
- IMS Question & Test Interoperability XML XDR;
- IMS Question & Test Best Practice & Implementation Guideline document.

This binding has been derived from the agreed IMS Q&TI Information Model Specification [QTI, 00a] and conforms to the XML Version 1.0 specification [XML, 98] of the W3C.

1.3 Structure of this Document

The structure of this document is:

2. XML BASICS	A brief description of the components within an XML schema;
3. DOCUMENT TYPE DEFINITION	The DTD used to describe the <i>Assessment</i> , <i>Section</i> and <i>Items</i> and defined as the IMS_QTI01.dtd;
4. EXAMPLE XML SCHEMA	Examples of the XML schema for <i>Assessments</i> , <i>Sections</i> and <i>Items</i> ;
5. META-DATA	The meta-data used to describe <i>Assessments</i> , <i>Sections</i> and <i>Items</i> .
APPENDIX A - DTD	A copy of the uncommented DTD;
APPENDIX B - XDR	A copy of the uncommented XDR;

1.4 Nomenclature

CDATA	Character Data
DTD	Document Type Definition
PCDATA	Parsed Character Data
Q&TI	Question & Test Interoperability
W3C	World Wide Web Consortium
XDR	XML Data Representation
XHTML	XML HyperText Mark-up Language

XML Extensible Markup Language

2. XML Basics

The Question & Test Interoperability data model can be defined as a hierarchy. Hierarchical models are convenient for representing data consisting of many elements and sub-elements. XML is perfectly suited for representing hierarchical models. An XML document is a hierarchy comprised of **elements** that have **contents** and **attributes**.

2.1 Elements

An element is a component of a document that has been identified in a way a computer can understand. Each element has a **tag name**. When a tag name is shown as “<TAGNAME>”, with less-than and greater-than symbols before and after the tag name, it serves as the **start-tag** to mark the beginning of an element. When that same tag name has a forward slash “/” added, it serves as an **end-tag** such as “</TAGNAME>”. An element may have contents between its start and end-tags and may have one or more **attributes**. When an XML element has a start and end-tag (also called an **opening** and **closing tag**) with a common name, it is considered to be “well-formed” XML. The contents of an element are placed between the start and end-tags as shown below:

```
<TAGNAME>contents</TAGNAME>
```

2.1.1 Element Contents

An element may contain other elements, Parsed Character Data (PCDATA), Character Data (CDATA), or a mixture of PCDATA and elements. The allowable contents of an element are its **content model**. PCDATA really means any character string that does not contain elements. PCDATA is what the bulk of elements will use between their start and end-tags. CDATA is different in that it is a method for adding any character data that should not be processed. For example, you could add some Java script code instructions using a CDATA section. A CDATA section tells the parser not to look for any markup until after it locates the end of the CDATA section.

2.1.2 Element Attributes

An attribute provides additional information about an element. Attributes are a way of attaching characteristics or properties to the elements of a document. An element may have more than one attribute and they are contained within the start tag of an element. Attributes are represented by an attribute name followed by an equal sign and the attribute value in quotation marks:

```
<timeframe>
  <begin restrict="1"> 1999-07-23 </begin>
</timeframe>
```

In this example the <timeframe> element contains another element, the <begin> element. The <begin> element has one attribute “restrict”, with the value 1. The value for the element <begin> is “1999-07-23”. These two elements then make up a ‘timeframe begin’ date.

2.1.3 Element Names

Each element has a unique name, referred to as the tag name. XML is case-sensitive in its processing of tag names. The IMS Question & Test Interoperability XML Binding Specification adheres to the following tag name rules:

- All tag names will conform to the rules for element naming as given within the XML Version 1.0 specification;
- Names beginning in “xml” in any case or mix of cases are not permitted;
- All element and attribute names in the IMS XML binding are aligned with the W3C XHTML standard and as such will be **lower-case**;
- Element names may not include words reserved by the XML specification. These include:

DOCTYPE
ELEMENT
ATTLIST
ENTITY

- Tag names defined within the IMS Q&TI XML Binding may not be redefined, with the exception of those that are used for extensions.

2.2 Document Type Definitions (DTD)

The *tag name*, *content model*, and *attributes* of elements are defined in a **Document Type Definition (DTD)** statement. These may exist as an external file or a block of text internal to an XML document. Internal DTDs are used to override elements defined in external DTD files, so an internal DTD should be used with care. The DTD defines the elements that may be used, and may define the contents of the elements.

This specification defines the **external DTD** with the file name (for version 1.0):

IMS_QTIV1p0.dtd

Some XML editors may make use of a DTD to help guide the developer in creating the proper elements at the proper locations in an XML file. Other developers will make use of the DTDs to validate their XML documents to ensure their document is consistent with all of the element names and locations defined in the DTD. An XML document is **valid** if it has an associated document type declaration and if the document complies with the constraints expressed in it. Details of the construction of DTDs are outside the scope of this document, but links to the [XML Version 1.0](#) specification are included in the References section of this document.

2.2.1 Declaring Element Contents

The information specifying the order and usage of allowable contents for an element are its **content model**. The content model is declared in a DTD (see below). The declaration of the content model is of the general form:

```
<!ELEMENT tagname (Content Model)>
```

The SHORT element can again serve as an example of how an element is declared with its content model:

```
<!ELEMENT short (#PCDATA)>
```

This element will contain character data (#PCDATA) that can be processed. The [XML Specification](#) provides more information about the details for creating and interpreting content models.

2.2.2 Declaring Element Attributes

An example of how the attributes for the element **assessment** is declared in a DTD is found below:

```
<!ELEMENT assessment (description, section+, objectives?, result,
                      extension?)>
<!ATTLIST assessment title CDATA #IMPLIED>
```

The first line declares that there is an element named **assessment** that must have the **description**, **section** and **result** elements and is additionally allowed to have **objectives** and/or **extension** elements as its contents. The second line begins with “**!ATTLIST**” to start an attribute list declaration for the **assessment** element. The word **title** will serve as the attribute’s name. The allowable value for this attribute must be of type CDATA.

At the end of the example above is the term IMPLIED. It is at this location in the attribute declaration, where a default value for an attribute may be specified. It is also possible to use the keyword REQUIRED which would force a TYPE value to be supplied and there would be no default value. In the example above, the IMPLIED designation means that the designer wants to allow users to omit the value for the attribute without forcing a particular default value.

2.2.3 Use of Attributes

Within the IMS XML binding, the use of attributes is reserved for information about the structure of the relevant data object. This means that an attribute is used to create a specific type of element e.g. the element could be the date and its attribute could be used to define the date as the date of birth.

Lists

A list is a repetition of the contents of an element. In XML, this is accomplished by repeating the containing element: for example, the **section** element contains an element **item**. Described in the DTD as:

```
<!ELEMENT section (item*, extension?)>
```

When instantiated in XML a repeating list of ITEM elements would appear:

```
<section>
  <item> "The first question set."</item>
  <item> "The second question set."</item>
</section>
```

In this example, the element **item** is repeated. Thus **item** is the *containing* element for *the repeated contents* descriptions. The notation for repetitions of an element in a content model follows the XML specification. An asterisk (*) specifies that *none or more* repetitions of the element may be included in the XML instantiation whereas a plus (+) specifies that *one or more* repetitions of the element may be included in the XML instantiation.

2.3 XML Schemas

A schema is a formal specification of element names that indicates which elements are allowed in an XML document, and in which combinations. New schema languages, such as those defined in the XML-Schemas Working Group, provide the same baseline functionality as a DTD. However, because these schema languages are extensible, developers can augment them with additional information, such as data types, inheritance and presentation rules. This makes these new schema languages far more powerful than DTDs. For more information about XML schemas, go to <http://www.w3.org/XML/Group/Schemas.html>.

This specification defines the **external XDR** with the file name (for version 1.0):

IMS_QTIV1p0.xdr

This specification defines an XML Data Representation (XDR). Some XML editors may make use of such a schema to help guide the developer in creating the proper elements at the proper locations in an XML file. Other developers will make use of the schema to validate their XML documents and/or to define extensions to the IMS Q&TI specification. Details of the construction of XDRs are outside the scope of this document.

2.4 Special Handling Requirements

2.4.1 XML Reserved Characters

Some characters used in XML must be escaped when used outside of their XML defined usage as found in Section 2.4 of the XML 1.0 Specification. These characters are ampersand (&), less than (<), greater than (>), apostrophe(') and the double-quotes character("). These characters may be represented using either numeric character references or the strings "&", "<", ">", "'", and """. Below is a more complete quote from the W3C XML specification:

Quote from Extensible Markup Language (XML) 1.0
W3C Recommendation 10-February-1998

2.4 Character Data and Markup

Text consists of intermingled character data and markup. Markup takes the form of start-tags, end-tags, empty-element tags, entity references, character references, comments, CDATA section delimiters, document type declarations, and processing instructions.

All text that is not markup constitutes the character data of the document.

The ampersand character (&) and the left angle bracket(<) may appear in their literal form only when used as markup delimiters or within a comment, a processing instruction or a CDATA section. They are also legal within the literal entity value of an internal entity declaration; see “4.3.2 Well-Formed Parsed Entities”. If they are needed elsewhere, they must be escaped using either numeric character references or the strings “&” and “<”

respectively. The right angle bracket (>) may be represented using the string “>” and must, for compatibility, be escaped using “>,” or a character reference when it appears in the string “[>” in content, when that string is not marking the end of a CDATA section.

In the content of elements, character data is any string of characters which does not contain the start delimiter of any markup. In a CDATA section, character data is any string of characters not including the CDATA-section-close delimiter, “[>”.

To allow attribute values to contain both single and double quotes, the apostrophe or single-quote character (') may be represented as “'”, and the double-quote character (") as “"”.

2.4.2 White Space Handling

Questions arise as to whether web-based data transmission tools might inadvertently strip-off or transform some of the white space characters embedded in the Enterprise data transmitted between systems using XML. To eliminate concern about this issue, refer to the following quote from the W3C XML standards, which indicate that all white space must be preserved where it is part of the data.

Quote from Extensible Markup Language (XML) 1.0
W3C Recommendation 10-February-1998

2.10 White Space Handling

In editing XML documents, it is often convenient to use “white space” (spaces, tabs, and blank lines, denoted by the non-terminal S in this specification) to set apart the markup for greater readability. Such white space is typically not intended for inclusion in the delivered version of the document. On the other hand, “significant” white space that should be preserved in the delivered version is common, for example in poetry and source code.

An XML processor must always pass all characters in a document that are not markup through to the application. A validating XML processor must also inform the application which of these characters constitute white space appearing in element content.

A special attribute named xml:space may be attached to an element to signal an intention that in that element, white space should be preserved by applications. In valid documents, this attribute, like any other, must be declared if it is used. When declared, it must be given as an enumerated type whose only possible values are “default” and “preserve”. For example:

```
<!ATTLIST poem xml:space (default | preserve)'preserve'>
```

The value “default” signals that applications’ default white-space processing modes are acceptable for this element; the value “preserve” indicates the intent that applications preserve all the white space. This declared intent is considered to apply to all elements within the content of the element where it is specified, unless overridden with another instance of the xml:space attribute.

2.5 Extensibility

Some providers will find the current element set defined in the Question & Test Interoperability specification too restrictive to accomplish their purposes. To ensure extensibility, the specification requires that there be no limit on potential extensions on major elements. An extension is the addition of information to an existing XML structure.

```
<!ELEMENT resp_extension ANY>
```

An example of the inclusion of **resp_extension** in the content model of element **presentation** is:

```
<!ELEMENT presentation (render_choice, render_hotspot, resp_extension?)>
```

The use of the **resp_extension** element is illustrated as follows:

```

<presentation>
    <render_choice> ... Multiple choice selections ... </render_choice>
    <render_hotspot> ... Image hot spot selections ... </render_hotspot>
    <resp_extension>
        <qticomment>This is a test to demo extensions</qticomment>
    </resp_extension>
</presentation>

```

The contents, but not a content model, of an extension must be declared in an internal or external DTD. Many extensions can be created through the use of existing elements. Care must be used with internal DTDs, as they override external DTD declarations. The content of an extension must obey the attribute and content models of the elements employed. New elements that duplicate the definitions of existing elements should not be introduced.

Prefacing the **resp_extension** element with an appropriate namespace may reference descriptions of extensions. For example, a group such as the Advanced Distributed Learning (ADL) initiative may wish to add the “adl” prefix to an extension element to uniquely identify ADL extensions. The following is an example of this:

```

<item>
    ... mandatory elements of item elements here ...
    <description lang= " en " >
        <short>Military psychometric question </short>
    </description>
    <extension adl:classification="Not classified"
               adl:title="Psychometric question">This example discusses how
               the psychometric questions are constructed for defence
               posts.
    </extension>
</item>

```

This serves to note the entire extension structure. Extensions should always be added at the lowest point (farthest from the root element) in the hierarchy possible, to the degree that the structure defines the meaning of the extension.

3. Document Type Definition

```

5. Meta-data Schema

The following meta-data elements are unique to the IMS Q&TI specifications. The elements declared within the IMS Meta-data Specifications are to be included where appropriate using whatever approach is suitable to the particular implementation. The issue of meta-data harmonisation with the other IMS specifications will be addressed in V2.0 of the IMS QTI Specifications.

5.1 Assessment Meta-data

```
<!ELEMENT assessmentmetadata (  
    qmd_absolutescore?,  
    qmd_assessmenttype?  
    qmd_feedbackavailable?  
    qmd_hintsavailable?,
