Abstract

- Java Server Pages allow special tags and java code to be embedded in HTML files. These tags and code are processed by the web server to obtain a dynamically-produced HTML page to the browser.
 - another architecture in the web-based distributed application arsenal.
 - produce dynamic web pages on the server side (as do servlets), but separate application logic from the appearance of the page.
 - the tags allow previously compiled java code, in the form of JavaBeans, to be used
 - allows fast development and testing.
 - may also produce XML documents, instead of HTML.

Development of JSP

- Java Server Pages were developed as a response to Microsoft's Active Server Pages (ASP). The main differences are that ASP only runs on Microsoft IIS and Personal Web Servers, and JSP has user-defined tags.
- Development dates: (Note that JSP is built on top of servlets)
 - Servlet 2.1 Jan. 99
 - JSP 1.0 June 99
 - Source code released to Apache to develop Tomcat server November 99
 - Servlet 2.2 and JSP 1.1 (J2EE1.2) December 99
 - Look for further development of tag library in 00.

JSP elements

- A JSP page looks like a standard HTML or XML page with additional elements processed by the JSP engine. Typically, these elements create text that is inserted into the resulting document.
- JSP elements
 - JSP directive passes information to the JSP engine, enclosed in `<% @ and %>` markers.
 - JSP actions or tags are a set of customized XML-style tags for particular actions, e.g. `jsp:useBean` instantiates the `JavaBean` class on the server.
 - Expression: anything between `<%= and %>` markers is evaluated by the JSP engine as a Java expression in the server environment.
 - Scriptlet: a small script in Java to perform other functions
 - Implicit Objects: servlet abstractions

Example JSP page

- This page prints the day of the month and year, and either “Good Morning” or Good Afternoon”, depending on the time.

```
<HTML>
```

```
<% @ page language="java" imports="com.wombat.JSP.*" %>
```

```
<H1>Welcome</H1>
```

```
<P>Today is </P>
```

```
<jsp:useBean id="clock" class="calendar.jspCalendar" />
```

```
<UL> <LI>Day: <%= clock.getDayOfMonth( ) %>
```

```
    <LI>Month: <%= clock.getYear( ) %>
```

```
</UL>
```

```
<% if (Calendar.getInstance( ).get(Calendar.AM_PM) == Calendar.AM)
```

```
    { %> Good Morning
```

```
      <% } else
```

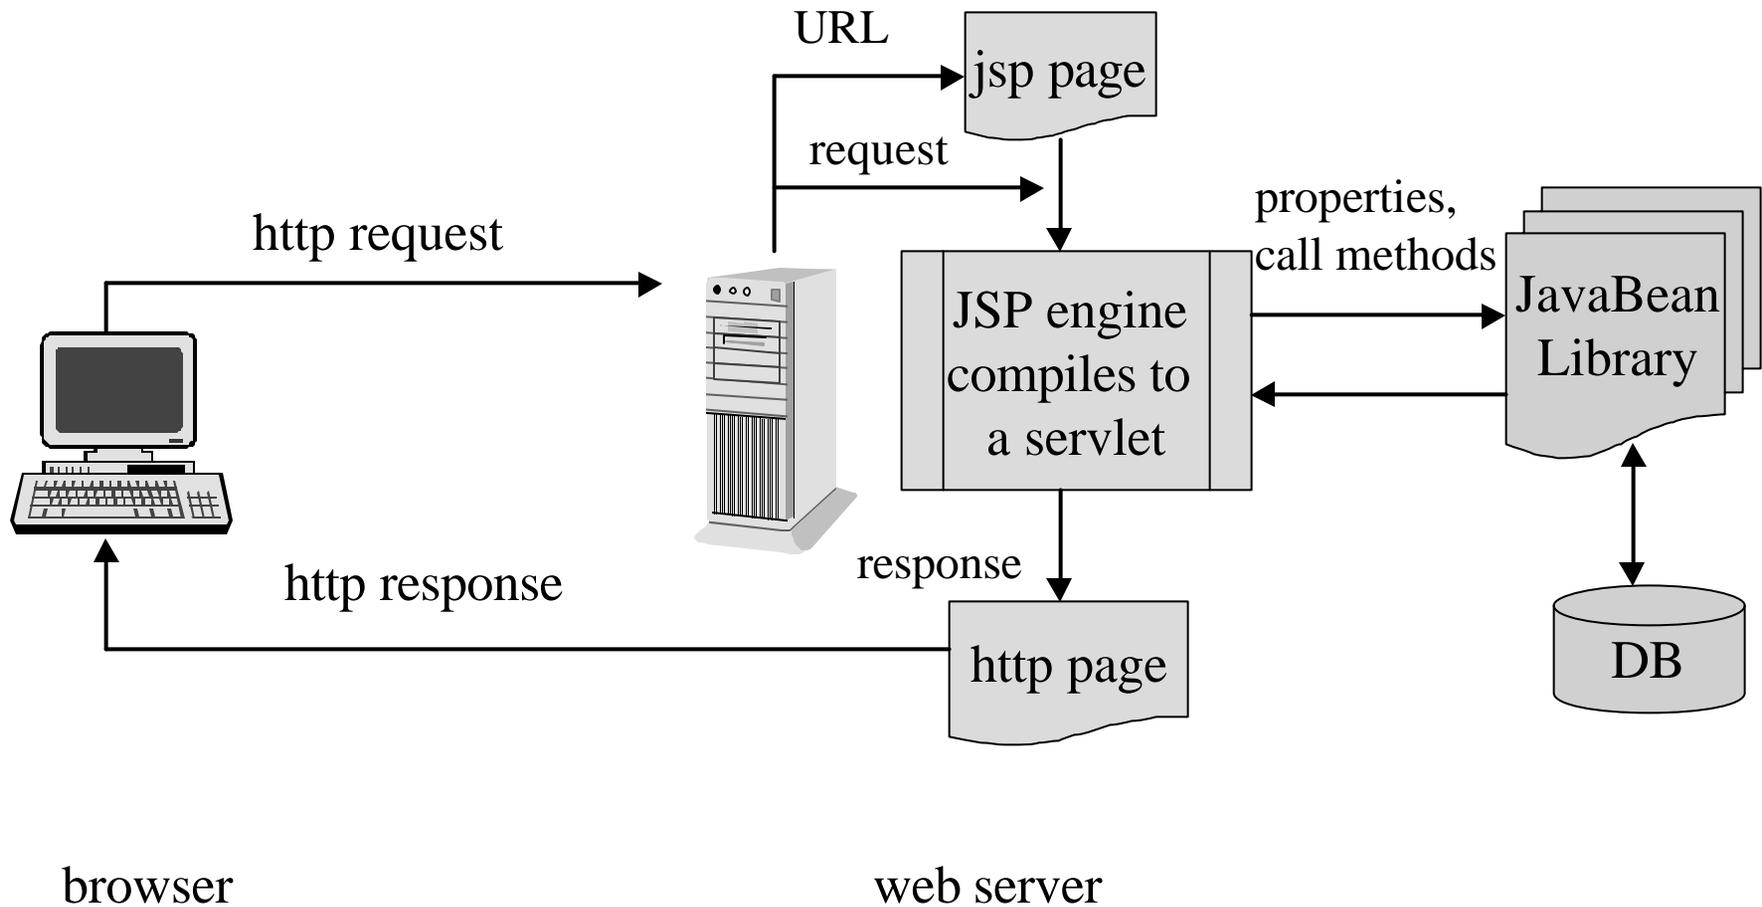

```
        { %> Good Afternoon
```

```
        <% } %>
```

```
<% @ include file = "copyright.html" %>
```

```
</HTML>
```

Architecture

JSP Directives

- page directives communicate page-specific information to the JSP engine, such as buffer or thread information or specify an error page.
- language directives specify script language + possible extensions
- include directive includes an external document in the page. These are often company information files or copyright files, but can also be jsp files.
- taglib directive indicates a library of custom tags that the page can invoke.
- (see helloworld.jsp example.)

JSP Tags

- There are a set of core JSP1.0 tags that implement JSP-technology specific operations. Additional standard tags are planned, and the user can design their own custom tags.
 - `jsp:useBean` - declares the usage of an instance of a JavaBeans component. If it does not already exist, then the instance is created and registered in the servlet environment. Several properties can be set; notably that the state of the bean is saved for the session or just the page..
 - `jsp:setProperty` - this tag can be used to set all the properties of a Bean from the request parameter stream with parameters of the same name, or can be used to set individual properties.
 - `jsp:getProperty` - gets the property of the Bean, converts it to a String, and puts it into the implicit object “out”.
 - `jsp:forward` - forwards the request to another jsp page or servlet.
 - `jsp:include` - include another jsp page
 - `jsp:plugin` - load into the specified plug-in of the browser

Scriptlets

- JSP pages can include small scripts in a page. These are code fragments that are executed at request time processing.
- May be combined with static elements on the page or other objects in the Java servlet environment.
- Anything contained with `<% and %>` or `<%! and %>` is evaluated by the script language engine, normally the Java virtual machine on the host.
- Declarations: the scope is the JSP file, including the include files. Declare variables or methods.
 - `<%! int a, b; double c = 0.0; %>`
 - `<%! Color c = new Color (0, 128, 255); %>`
- Expressions: any language expression, casts result to a String
 - `<% = Math.sqrt(2) %>`

More on Scriptlets

- Note that expressions never have semicolons.
- Scriptlets within `<%` and `%>` can have declarations, expressions, or any other kind of code fragment.
 - `<% String name = null;`
 `if (request.getParameter("name") == null)`
 `{`
 `%>`
 - you can use any of the JSP implicit objects or classes imported by the page directive, declared in a declaration, or named in a `<jsp:useBean>` tag.

Processing HTML Forms by Servlets

- In the form tag on the HTML page, you can put the action field to be a JSP page.
- This is compiled to be a servlet and the request and response parameters can be explicitly used in a scriptlet on the page.
 `request.getParameter("username");`
 where username is the name of a field on the form.
- The request object implements `javax.servlet.HttpServletRequest` and has the following methods, among others:
 - `getRequest`
 - `getParameterNames`
 - `getParameterValues`
 - `getParameter`

Processing HTML Forms by JavaBeans

- If using a Bean to process the form data, no action tag is necessary on the form.
- Give form element names that correspond to properties in the bean (exactly, respecting upper and lower case).
- First give the useBean tag to instantiate the Bean.
- Then give the setProperty tag either to set all properties, if all form elements names are included in the bean's properties, or to set individual ones.

```
<jsp:useBean id="numguess" class="num.NumberGuessBean"
                                                    scope="session"/>
```

```
<jsp:setProperty name="numguess" property="*/>
```

- Similarly, you can retrieve data from a bean property and use it in the resulting html page:

```
<H1> Hello <jsp:getProperty name="mybean" property="username"/>!
```

```
</H1>
```

Using with XML

- JSP pages can be used to generate XML pages.
- The JSP specification provides a way for XML tools to author and manipulate JSP pages, by converting JSP tags to their XML equivalents.
 - add a JSP root element to the document
 - convert elements and directives to their XML equivalent, e.g. instead of `<% and %>` scriptlet markers, use `<jsp:scriptlet>` and `</jsp:scriptlet>` XML tags.
 - create CDATA elements for all other (typically non-JSP) elements on the page

Industry Support

- Servers: Apache, iPlanet Web, IBM WebSphere, BEA WebLogic, Inprise Application Server, ATG DYnamo, Acme, Bluestone, Gemstone, Oracle
- Tools: Forte SynerJ, Oracle Jdeveloper, Inprise Jbuilder, Macromedia Drumbeat 2000, NetObjects Fusion, Symantic Visual Café, . . .
- Engines:
 - ServletExec for IIS, Netscape, all MacOS servers
 - JRun for IIS, Netscape, Apache, WebSite Pro, WebSTAR
 - WAICoolRunner for Netscape
 - Caucho Resin for Apache, IIS

Community Process

- Java Community has put out Java Specification Request (JSR) for next version “Dot.next” JSP and Servlets, Standard Tag Library.
- Drafts will be posted for review at all levels: expert, participant, public
- Goals include support for
 - application events
 - improved debugging and tool support
 - improved XML support
 - improved JSP authoring support
 - better composition of components
 - . . .

JSP Resources

- Sun: java.sun.com/products/jsp
 - links for downloads, tutorials, white paper, etc.
 - join community process
 - JSP syntax card
- Apache:
 - download apache web server: www.apache.org
 - Jakarta project for Java-based web servers, including an apache module for JSP and servlets: jakarta.apache.org
